

Inter-computer communication

• Without shared memory, computers need to communicate

Direct link

Direct link

Direct links aren't practical – they don't scale

1

Connecting computers

Communication network

Share the infrastructure

Collision: when two nodes transmit at the same time, same channel
Both signals get damaged

Multiple access problem

How do you coordinate multiple senders?

Modes of connection

Circuit-switching (virtual circuit)

Dedicated path (route) – established at setup

Guaranteed (fixed) bandwidth – routers commit to resources

Typically fixed-length packets (cells) – each cell only needs a virtual circuit ID

Constant latency

This is what IP uses

Packet-switching (datagram)

Shared connection; competition for use with others

Data is broken into chunks called packets

Each packet contains a destination address

available bandwidth ≤ channel capacity

Variable latency

3

Packet switching

Random access

- Statistical multiplexing

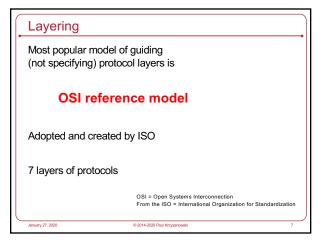

- No timeslots

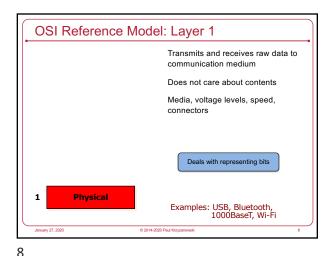

- Anyone can transmit when ready

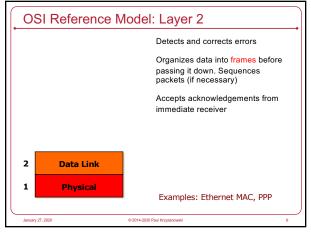

- But be prepared for collisions or dropped packets

Packet-based protocol
Originally designed for shared (bus-based) links
Each endpoint has a unique ethernet address
MAC address: 48-bit number

6

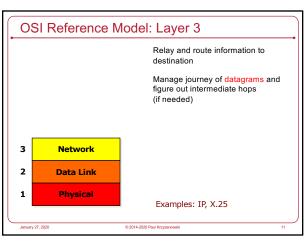

OSI Reference Model: Layer 2 An ethernet switch is an example of a device that works on layer 2 It forwards ethernet frames from one host to another as long as the hosts are connected to the switch (switches may be cascaded) This set of hosts and switches defines the local area network (LAN) **Data Link Physical**

9

OSI Reference Model: Layer 4 Provides an interface for end-toend (application-to-application) communication: sends & receives segments of data. Manages flow control. May include end-to-end reliability Network interface is similar to a Transport 3 Network 2 Data Link **Physical**

Examples: TCP, UDP

13

A layer communicates with its counterpart Logical View Application 7 **Application** Presentation Presentation 6 Session Session **Transport Transport** Network Network **Data Link Data Link** 2 Physical Physical

15

Ethernet service guarantees · Each packet (frame) contains a CRC checksum - Recipient will drop the received frame if it is bad · No acknowledgement of packet delivery • Unreliable, in-order delivery - Packet loss possible

18

17

20

22

We want to communicate beyond the LAN Wan = Wide Area Network Network Layer Responsible for routing between LANs The Internet Evolved from ARPANET (1969) Internet = global network of networks based on the Internet Protocol (IP) family of protocols

Internet Protocol

A set of protocols designed to handle the interconnection of many local and wide-area networks that together comprise the Internet

IPv4 & IPv6: network layer

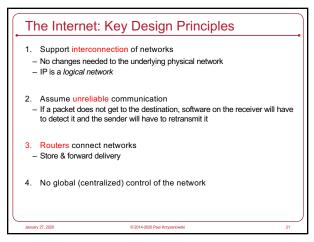

Other IP-based protocols include TCP, UDP, RSVP, ICMP, etc.

Relies on routing from one physical network to another

IP is connectionless
No state needs to be saved at each router

Survivable design: support multiple paths for data
... but packet delivery is not guaranteed!

19

Routers tie LANs together into one Internet

Tier 3 ISP

Tier 2 ISP

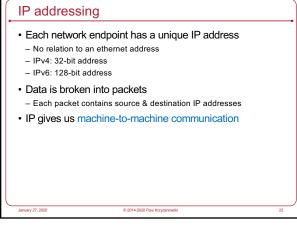

Tier 2 ISP

A packet may pass through many networks – within and between ISPs

21

Transport Layer: UDP & TCP

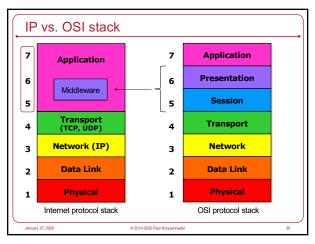

23 24

26

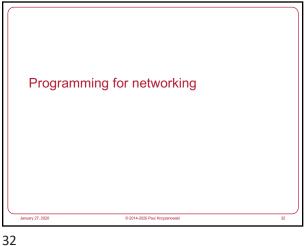

IP transport layer protocols IP gives us two transport-layer protocols for communication - TCP: Transmission Control Protocol · Connection-oriented service - operating system keeps state · Full-duplex connection: both sides can send messages over the same link · Reliable data transfer: the protocol handles retransmission . In-order data transfer: the protocol keeps track of sequence numbers Flow control: receiver stops sender from sending too much data Congestion control: "plays nice" on the network – reduce transmission rate · 20-byte header – UDP: User Datagram Protocol . Connectionless service: lightweight transport layer over IP Data may be lost · Data may arrive out of sequence · Checksum for corrupt data: operating system drops bad packets · 8-byte header

25

Protocol Encapsulation At any layer - The higher level protocol headers are just treated like data An ethernet switch or ethernet driver sees this A router or IP driver sees this: TCP payload

30

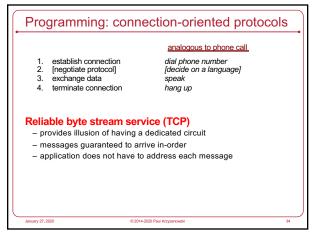

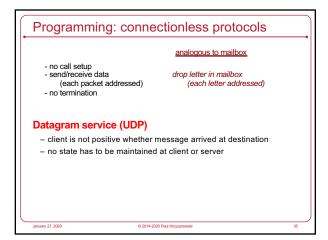

Network API • App developers need access to the network • A Network Application Programming Interface (API) provides this Core services provided by the operating system · Operating System controls access to resources - Libraries may handle the rest

33

Paul Krzyzanowski 5

31

34

• Dominant A

- Dominant API for transport layer connectivity
- Created at UC Berkeley for 4.2BSD Unix (1983)
- Design goals
- Communication between processes should not depend on whether they are on the same machine
- Communication should be efficient
- Interface should be compatible with files
- Support different protocols and naming conventions
- · Sockets is not just for the Internet Protocol family

36

What is a socket?

Abstract object from which messages are sent and received

Looks like a file descriptor

Application can select particular style of communication

Virtual circuit (connection-oriented), datagram (connectionless), message-based, in-order delivery

Unrelated processes should be able to locate communication endpoints

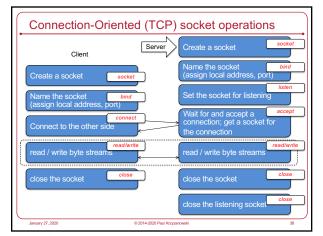

Sockets can have a name

Name should be meaningful in the communications domain

E.g., Address & port for IP communications
