Week 9: Distributed Databases

Part 1: Google Bigtable
Bigtable

- Highly available distributed storage
- Built with semi-structured data in mind
  - URLs: content, metadata, links, anchors, page rank
  - User data: preferences, account info, recent queries
  - Geography: roads, satellite images, points of interest, annotations

- Large scale
  - Petabytes of data across thousands of servers
  - Billions of URLs with many versions per page
  - Hundreds of millions of users
  - Thousands of queries per second
  - 100TB+ satellite image data

Abstract

Bigtable is a distributed storage system for managing structured data that is designed to scale to a very large size, petabytes of data across thousands of commodity servers. Many projects at Google store data in Bigtable, including web indexing, Google Earth, and Google Finance. These applications place very different demands on Bigtable, both in terms of data size (from URLs to web pages to satellite images) and latency requirements (from backend bulk processing to real-time data serving). Despite these varied demands, Bigtable has successfully provided a flexible, high-performance solution for all of these Google products. In this paper we describe the simple data model provided by Bigtable, which gives clients dynamic control over data layout and format, and we describe the design and implementation of Bigtable.

1 Introduction

Over the last two and a half years we have designed, implemented, and deployed a distributed storage system for managing structured data as Google called Bigtable. Bigtable is designed to reliably scale to petabytes of data across thousands of machines. Bigtable has achieved several goals: wide applicability, scalability, high performance, and high availability. Bigtable is used by more than sixty Google products and projects, including Google Analytics, Google Finance, Orkut, Personalized Search, Verify, and Google Earth. These products use Bigtable for a variety of demanding workloads, which range from throughput-oriented batch-processing jobs to latency-sensitive serving of data to end users. The Bigtable clusters used by these products span a wide range of configurations, from a handful to thousands of servers, and store up to several hundred terabytes of data.

In many ways, Bigtable resembles a database in that it stores many implementation strategies with databases. Parallel databases [14] and main-memory databases [13] have achieved scalability and high performance, but Bigtable provides a different interface than most systems. Bigtable does not support a full relational data model; instead, it provides clients with a simple data model that supports dynamic control over data layout and format, and allows clients to reason about the locality properties of the data represented in the underlying storage. Data is indented using row and column names that can be arbitrary strings. Bigtable also treats data as uninterpreted strings, although clients often serialize various forms of structured and semi-structured data into these strings. Clients can control the locality of their data through careful choices in their schemas. Finally, Bigtable schema parameters let clients dynamically control whether to serve data out of memory or from disk.

Section 2 describes the data model in more detail, and Section 3 provides an overview of the client API. Section 4 briefly describes the underlying Google infrastructure on which Bigtable depends. Section 5 describes the fundamentals of the Bigtable implementation, and Section 6 describes some of the refinements that we made to improve Bigtable’s performance. Section 7 provides measurements of Bigtable’s performance. We describe several examples of how Bigtable is used at Google in Section 8, and discuss some lessons we learned in designing and supporting Bigtable in Section 9. Finally, Section 10 describes related work, and Section 11 presents our conclusions.

2 Data Model

A Bigtable is a sparse, distributed, persistent multi-dimensional sorted map. The map is indexed by a row key, column key, and a timestamp; each value in the map is an uninterpreted array of bytes.

\[(rowstring, columnstring, timeint64) -> string\]
Uses

At Google, used for:
- Google Analytics
- Google Finance
- Personalized search
- Blogger.com
- Google Code hosting
- YouTube
- Gmail
- Google Earth & Google Maps
- Dozens of others… over sixty products
Bigtable is NOT a relational database

Bigtable appears as a large table

“A Bigtable is a sparse, distributed, persistent multidimensional sorted map”*

<table>
<thead>
<tr>
<th>rows</th>
<th>columns</th>
</tr>
</thead>
<tbody>
<tr>
<td>com.aaa</td>
<td>EN</td>
</tr>
<tr>
<td>com.cnn.www</td>
<td>EN</td>
</tr>
<tr>
<td>com.cnn.www/TECH</td>
<td>EN</td>
</tr>
<tr>
<td>com.weather</td>
<td>EN</td>
</tr>
</tbody>
</table>

Web table example

*Bigtable: OSDI 2006
(row, column, timestamp) → cell contents
- Contents are arbitrary strings (arrays of bytes)

```
<table>
<thead>
<tr>
<th>row</th>
<th>language:</th>
<th>contents:</th>
</tr>
</thead>
<tbody>
<tr>
<td>com.aaa</td>
<td>EN</td>
<td></td>
</tr>
<tr>
<td>com.cnn.www</td>
<td>EN</td>
<td>&lt;!DOCTYPE html&gt;</td>
</tr>
<tr>
<td>com.cnn.www/TECH</td>
<td>EN</td>
<td>&lt;!DOCTYPE html&gt;</td>
</tr>
<tr>
<td>com.weather</td>
<td>EN</td>
<td>&lt;!DOCTYPE html&gt;</td>
</tr>
</tbody>
</table>
```

*Web table example*
Column Family

- Group of column keys ⇒ basic unit of data access
  - Data in a column family is typically of the same type
  - Implementation of bigtable compresses data in the same column family

• Operations
  - (1) Create column family ⇒ this is an admin task done when table is created
  - (2) Store data in any key within the family ⇒ this can be done anytime

• There will typically be a small number of column families
  - ≤ hundreds of column families
  - A table may have an unlimited # of columns: often sparsely populated

• Identified by family:qualifier
Three column families

- **“language:”** – language for the web page
- **“contents:”** – contents of the web page
- **“anchor:”** – contains text of anchors that reference this page

  - www.cnn.com is referenced by Sports Illustrated (cnnsi.com) and My-Look (mlook.ca)

<table>
<thead>
<tr>
<th>Column family</th>
<th>“language:”</th>
<th>“contents:”</th>
<th>anchor:cnnsi.com</th>
<th>anchor:mlook.ca</th>
</tr>
</thead>
<tbody>
<tr>
<td>com.aaa</td>
<td>EN</td>
<td>&lt;!DOCTYPE html PUBLIC...</td>
<td></td>
<td></td>
</tr>
<tr>
<td>com.cnn.www</td>
<td>EN</td>
<td>&lt;!DOCTYPE HTML PUBLIC...</td>
<td></td>
<td></td>
</tr>
<tr>
<td>com.cnn.www/TECH</td>
<td>EN</td>
<td>&lt;!DOCTYPE HTML&gt;...</td>
<td>“CNN”</td>
<td>“CNN.com”</td>
</tr>
<tr>
<td>com.weather</td>
<td>EN</td>
<td>&lt;!DOCTYPE HTML&gt;...</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
Tables & Tablets

• Row operations are atomic

• Table partitioned dynamically by rows into tablets

• Tablet = range of contiguous rows
  – Unit of distribution and load balancing
  – Nearby rows will usually be served by the same server
  – Accessing nearby rows requires communication with a small # of machines
  – You need to select row keys to ensure good locality
    • E.g., reverse domain names:
Table splitting

- A table starts as one tablet
- As it grows, it is split into multiple tablets
  - Approximate size: 100-200 MB per tablet by default

<table>
<thead>
<tr>
<th></th>
<th>“language:”</th>
<th>“contents:”</th>
</tr>
</thead>
<tbody>
<tr>
<td>com.aaa</td>
<td>EN</td>
<td>&lt;!DOCTYPE html PUBLIC...</td>
</tr>
<tr>
<td>com.cnn.www</td>
<td>EN</td>
<td>&lt;!DOCTYPE HTML PUBLIC...</td>
</tr>
<tr>
<td>com.cnn.www/TECH</td>
<td>EN</td>
<td>&lt;!DOCTYPE HTML&gt;...</td>
</tr>
<tr>
<td>com.weather</td>
<td>EN</td>
<td>&lt;!DOCTYPE HTML&gt;...</td>
</tr>
</tbody>
</table>

*tablet*
## Splitting a tablet

<table>
<thead>
<tr>
<th>Domain</th>
<th>Language</th>
<th>Contents:</th>
</tr>
</thead>
<tbody>
<tr>
<td>com.aaa</td>
<td>EN</td>
<td>&lt;!DOCTYPE html PUBLIC…</td>
</tr>
<tr>
<td>com.cnn.www</td>
<td>EN</td>
<td>&lt;!DOCTYPE HTML PUBLIC…</td>
</tr>
<tr>
<td>com.cnn.www/TECH</td>
<td>EN</td>
<td>&lt;!DOCTYPE HTML&gt;…</td>
</tr>
<tr>
<td>com.weather</td>
<td>EN</td>
<td>&lt;!DOCTYPE HTML&gt;…</td>
</tr>
<tr>
<td>com.wikipedia</td>
<td>EN</td>
<td>&lt;!DOCTYPE HTML&gt;…</td>
</tr>
<tr>
<td>com.zcorp</td>
<td>EN</td>
<td>&lt;!DOCTYPE HTML&gt;…</td>
</tr>
<tr>
<td>com.zoom</td>
<td>EN</td>
<td>&lt;!DOCTYPE HTML&gt;…</td>
</tr>
</tbody>
</table>
Timestamps

• Each column family may contain multiple versions

• Version indexed by a 64-bit timestamp
  – Real time or assigned by client

• Per-column-family settings for garbage collection
  – Keep only latest \( n \) versions
  – Or keep only versions written since time \( t \)

• Retrieve most recent version if no version specified
  – If specified, return version where timestamp \( \leq \) requested time
API: Operations on Bigtable

• Create/delete tables & column families
• Change cluster, table, and column family metadata (e.g., access control rights)
• Write or delete values in cells
• Read values from specific rows
• Iterate over a subset of data in a table
  – All members of a column family
  – Multiple column families
    • E.g., regular expressions, such as anchor:*.cnn.com
  – Multiple timestamps
  – Multiple rows

• Atomic read-modify-write row operations
• Allow clients to execute scripts (written in Sawzall) for processing data on the servers
Implementation: Supporting Services

• **GFS**
  – For storing log and data files

• **Cluster management system**
  – For scheduling jobs, monitoring health, dealing with failures

• **Google SSTable (Sorted String Table)**
  – Internal file format optimized for streaming I/O and storing <key,value> data
  – Provides a persistent, ordered, *immutable* map from keys to values
    • Append-only
    – Memory or disk based; indexes are cached in memory
  – If there are additions/deletions/changes to rows
    • New SSTables are written out with the deleted data removed
    • Periodic compaction merges SSTables and removes old retired ones

See [http://goo.gl/McD6ex](http://goo.gl/McD6ex) for a description of SSTable
[https://www.igvita.com/2012/02/06/sstable-and-log-structured-storage-leveldb/](https://www.igvita.com/2012/02/06/sstable-and-log-structured-storage-leveldb/)
Chubby is used to:

- Ensure there is only one active master
- Store bootstrap location of Bigtable data
- Discover tablet servers
- Store Bigtable schema information
- Store access control lists
Implementation

1. Many tablet servers – coordinate requests to tablets
   - Can be added or removed dynamically
   - Each manages a set of tablets (typically 10-1,000 tablets/server)
   - Handles read/write requests to tablets
   - Splits tablets when too large

2. One master server
   - Assigns tablets to tablet server
   - Balances tablet server load
   - Garbage collection of unneeded files in GFS
   - Schema changes (table & column family creation)

3. Client library
Client data does not move though the master
Clients communicate directly with tablet servers for reads/writes
Implementation: METADATA table

Three-level hierarchy
- Balanced structure similar to a B+ tree
- Root tablet contains location of all tablets in a special METADATA table
- Row key of METADATA table contains location of each tablet
  \( f(\text{table}_I, \text{end}_row) \Rightarrow \text{location of tablet} \)
• Tablet assigned to one tablet server at a time

• When master starts:
  – Grabs a unique master lock in Chubby (prevent multiple masters)
  – Scans the servers directory in Chubby to find live tablet servers
  – Contacts each tablet server to discover what tablets are assigned to that server
  – Scans the METADATA table to learn the full set of tablets
    • Build a list of tablets not assigned to servers
      – These will be assigned by choosing a tablet server & sending it a tablet load request
Fault Tolerance

Fault tolerance is provided by GFS & Chubby

• Dead tablet server
  – Master is responsible for detecting when a tablet server is not working
    • Asks tablet server for status of its lock
    • If the tablet server cannot be reached or has lost its lock
      – Master attempts to grab that server’s lock
      – If it succeeds, then the tablet server is dead or cannot reach Chubby
      – Master moves tablets that were assigned to that server into an unassigned state

• Dead master
  – Master kills itself when its Chubby lease expires
  – Cluster management system detects a non-responding master

• Chubby: designed for fault tolerance (5-way replication)

• GFS: stores underlying data – designed for $n$-way replication
• Each table can be configured for replication to multiple Bigtable clusters in different data centers

• Bigtable uses an eventual consistency model
  – Replicas may be updated asynchronously
Sample applications

Google Analytics

- Raw Click Table (~200 TB)
  - Row for each end-user session
  - Row name: {website name and time of session}
    - Sessions that visit the same web site are sorted & contiguous

- Summary Table (~20 TB)
  - Contains various summaries for each crawled website
  - Generated from the Raw Click table via periodic MapReduce jobs
Sample applications

Personalized Search

• One Bigtable row per user (unique user ID)

• Column family per type of action
  – E.g., column family for web queries (your entire search history!)

• Bigtable timestamp for each element identifies when the event occurred

• Uses MapReduce over Bigtable to personalize live search results
Sample applications

- Google Maps / Google Earth
  - Preprocessing
    - Table for raw imagery (~70 TB)
    - Each row corresponds to a single geographic segment
    - Rows are named to ensure that adjacent segments are near each other
    - Column family: keep track of sources of data per segment
      (this is a large # of columns – one for each raw data image – but sparse)
  - MapReduce used to preprocess data
  - Serving
    - Table to index data stored in GFS
    - Small (~500 GB) but serves tens of thousands of queries with low latency
Bigtable outside of Google

Apache HBase

- Built on the Bigtable design
- Small differences (may disappear)
  - Access control not enforced per column family
  - Millisecond vs. microsecond timestamps
  - No client script execution to process stored data
  - Built to use HDFS or any other file system
  - No support for memory mapped tablets
  - Improved fault tolerance with multiple masters on standby
Bigtable vs. Amazon Dynamo

- Dynamo targets apps that only need key/value access with a primary focus on high availability
  - *key-value store versus column-store*
    (column families and columns within them for each key that's accessed)
  - Bigtable: distributed DB built on GFS
  - Dynamo: distributed hash table
  - Bigtable supports iterating over rows in a table
  - Updates are not rejected even during network partitions or server failures
The End
