Week 13: Infrastructure

Part 3: High Performance Computing (HPC) Clusters
2021's most powerful supercomputer: Fugaku 富岳 – Japan – developed by RIKEN & Fujitsu

- **Performance**
  - 442 petaflops
  - Fujitsu A64FX SoC processors: 7.6 million ARM cores

- **OS**
  - Compute nodes run McKernel (lightweight kernel designed for HPC) – a few hundred lines of C++
  - Communicate with I/O nodes that run Linux

- **Communication**
  - Torus Fusion (tofu) – proprietary interconnect developed by Fujitsu
    - 6-dimensional mesh/torus topology – full-duplex link with peak bandwidth of 5 GB/s in each direction

- **Storage**
  - 1.6 TB NVMe SSD for every 16 nodes
  - 150 PB shared storage – Lustre FS

https://en.wikipedia.org/wiki/Fugaku_(supercomputer)
Supercomputers

2018’s Most powerful supercomputer: IBM AC922 – Summit at Oak Ridge National Laboratory

- 189 petaflops, >10PB memory
- 4,608 nodes
  - 6 NVIDIA Volta V100s GPUs
  - 2 IBM POWER9™ CPUs
  - 512 GB DDR4 + 96GB HBM2 RAM
  - 1600GB NV memory
  - 42 teraflops per node

- >27,000 GPUs
- >9,000 CPUs

- 100G InfiniBand interconnect
- 250 PB 2.5 TB/s file system
- OS: Red Hat Enterprise Linux
- Peak power consumption: 13 MW

See https://www.olcf.ornl.gov/summit/
• Supercomputers are *not* distributed computers
• Lots of processors connected by high-speed networks
• Shared memory access
• Shared operating system (all TOP500 run Linux)
Supercomputing clusters

• Supercomputing cluster
  – Build a supercomputer from commodity computers & networks
  – A distributed system

• Target complex, typically scientific, applications:
  – Large amounts of data
  – Lots of computation
  – Parallelizable application

• Many custom efforts
  – Typically Linux + message passing software + remote exec + remote monitoring
Cluster Interconnects
Cluster Interconnect

Provide communication between nodes in a cluster

Goals

- Low latency
  - Avoid OS overhead, layers of protocols, retransmission, etc.

- High bandwidth
  - High bandwidth, switched links
  - Avoid overhead of sharing traffic with non-cluster data

- Low CPU overhead

- Low cost
  - Cost usually matters if you’re connecting thousands of machines

  - Usually a LAN is used: best $/performance ratio
Cluster Interconnect

Assume:
- 10 Gbps per server
- 40 servers per rack
  ⇒ 400 Gbps/rack

16 racks ⇒ 8 Tbps

Max switch capacity currently ~ 5 Tbps
  ⇒ Need at least two cluster switches
Switches add latency

Within one rack
- One switch latency $\approx 1\ldots8 \mu s$ for a 10 Gbps switch
- Two links (to switch + from switch) @ 1-2 meters of cable
  - Propagation time in copper $\approx 2 \times 10^8 \text{ m/s} \approx 5 \text{ ns/m}$

Between racks in a cluster
- Three switch latency ($\approx 3\ldots24 \mu s$)
- 4 links (to rack switch + to cluster switch + back to target rack)
- ~10-100 meters distance (50 ... 500 ns)

Add to that the normal latency of sending & receiving packets:
- System latency of processing the packet, OS mode switch, queuing the packet, copying data to the transceiver, …
- Serialization delay = time to copy packet to media $\approx 1 \mu s$ for a 1KB packet on a 10 Gbps link
TCP adds latency

- Operating system overhead, queueing, checksums, acknowledgements, congestion control, fragmentation & reassembly, …
- Lots of interrupts
- Consumes time & CPU resources

How about using a high-speed LAN without the overhead?

- LAN dedicated for intra-cluster communication
  - Sometimes known as a System Area Network (SAN)
- Dedicated network for storage: Storage Area Network (SAN)
Example High-Speed Interconnects

Common traits
- **TCP/IP Offload Engines (TOE)**
  - TCP stack at the network card
- **Remote Direct Memory Access (RDMA)**
  - memory copy with no CPU involvement

**Intel I/O Acceleration Technology (I/OAT)** – combines TOE & RDMA
- Data copy without CPU, TCP packet coalescing, low-latency interrupts, …
Example: **InfiniBand**
- Switch-based point-to-point bidirectional serial links
- Link processors, I/O devices, and storage
- Each link has one device connected to it
- Enables data movement via *remote direct memory access* (RDMA)
  - No CPU involvement!
- Up to 250 Gbps/link
  - Links can be aggregated: up to 3000 Gbps with 12x links

**IEEE 802.1 Data Center Bridging (DCB)**
- Set of standards that extend Ethernet
- Lossless data center transport layer
  - Priority-based flow control, congestion notification, bandwidth management
Programming tools for HPC: PVM

**PVM** = Parallel Virtual Machine

- Software that emulates a general-purpose heterogeneous computing framework on interconnected computers

- Model: **app = set of tasks**
  - **Functional parallelism**: tasks based on function: input, solve, output
  - **Data parallelism**: tasks are the same but work on different data

- PVM presents library interfaces to:
  - Create tasks
  - Use global task IDs
  - Manage groups of tasks
  - Pass basic messages between tasks
MPI: Message Passing Interface

- API for sending/receiving messages
  - Optimizations for shared memory & NUMA
  - Group communication support

- Other features:
  - Scalable file I/O
  - Dynamic process management
  - Synchronization (barriers)
  - Combining results
HPC Cluster Example

Early example: Early (>20 years old!) effort on Linux – Beowulf

- Initially built to address problems associated with large data sets in Earth and Space Science applications
- From Center of Excellence in Space Data & Information Sciences (CESDIS)
  - Division of University Space Research Association at the Goddard Space Flight Center
- Still used!

This isn’t one fixed package

- Just an example of putting tools together to create a supercomputer from commodity hardware
What makes it possible?

- Commodity off-the-shelf computers are cost effective
- Publicly available software:
  - Linux, GNU compilers & tools
  - MPI (message passing interface)
  - PVM (parallel virtual machine)
- Low cost, high speed networking
- Experience with parallel software
  - Difficult: solutions tend to be custom
What can you run?

• Programs that do not require fine-grain communication

• Basic properties
  – Nodes are dedicated to the cluster
    • Performance of nodes not subject to external factors
  – Interconnect network isolated from external network
    • Network load is determined only by application
  – Global process ID provided
    • Global signaling mechanism
HPC Cluster Example

• 18 admin tools
• 3 compiler families (GNU, Intel, LLVM)
• 13 development tool packages (EasyBuild, cbuild, libtool, …)
• Lua scripting language & supporting packages
• 8 I/O libraries
  – Adios – enables defining how data is accessed
  – HDF5 – data model, library, and file format for storing and managing data
  – NetCDF – managing array-oriented scientific data
• Lustre file system
• 4 MPI packages
• 12 parallel libraries
• 14 performance tools
• Provisioning tools, resource management, runtime packages
• 6 threaded library packages

http://openhpc.community
HPC example: Rocks Cluster Distribution

- Employed on over 1,900 clusters ([https://app.awesome-table.com/-KIAGPC-2IYjiVG2ReJn/view](https://app.awesome-table.com/-KIAGPC-2IYjiVG2ReJn/view))
- Mass installation is a core part of the system
  - Mass re-installation for application-specific configurations
- Front-end central server + compute & storage nodes
- Based on CentOS Linux
- Rolls: collection of packages
  - Base roll includes: PBS (portable batch system), PVM (parallel virtual machine), MPI (message passing interface), job launchers, …
Batch Processing
Batch processing

• Non-interactive processes
  – Schedule, run eventually, collect output

• Examples:
  – MapReduce, many supercomputing tasks
    (circuit simulation, climate simulation, weather)
  – Graphics rendering
    • Maintain a queue of frames to be rendered
    • Have a dispatcher to remotely exec process

• In many cases – minimal or no IPC needed

• Coordinator dispatches jobs
Example – Pixar:

- 55,000 cores running RedHat Linux and Renderman (2018)
- Custom Linux software for articulating, animating/lighting (Marionette), scheduling (Ringmaster), and rendering (RenderMan)

- Toy Story
  - Each frame took between 45 minutes to 30 hours to render: 114,240 total frames
  - 117 computers running 24 hours a day
  - Toy Story 4 – 24 years later: 50-150 hours to render each frame

- Took over two years (in real time) to render Monsters University (2013)
  - Sully has over 1 million hairs – each rendered distinctly & motion animated

- Average time to render a single frame
  - Cars (2006): 8 hours
  - Cars 2 (2011): 11.5 hours
  - Disney/Pixar’s Coco – Up to 100 hours to render one frame
Batch Processing

• OpenPBS.org:
  – Portable Batch System
  – Developed by Veridian MRJ for NASA

• Commands
  – Submit job scripts
    • Submit interactive jobs
    • Force a job to run
  – List jobs
  – Delete jobs
  – Hold jobs
Load Balancing
 Functions of a load balancer

• Load balancing

• Failover

• Planned outage management
Redirection

Redirection

Simplest technique

HTTP REDIRECT error code

www03.mysite.com
Redirection

• Trivial to implement

• Successive requests automatically go to the same web server
  – Important for sessions

• Visible to customer
  – Don’t like the changing URL

• Bookmarks will usually tag a specific site
Load balancing router

- As routers got smarter
  - Not just simple packet forwarding
  - Most support packet filtering
  - Add load balancing to the mix

- This includes most IOS-based Cisco routers, Radware Alteon, F5 Big-IP
Load balancing router

• Assign one or more virtual addresses to physical address
  – Incoming request gets mapped to physical address

• Special assignments can be made per port
  – e.g., all FTP traffic goes to one machine

• **Balancing decisions:**
  – Pick machine with least # TCP connections
  – Factor in weights when selecting machines
  – Pick machines round-robin
  – Pick fastest connecting machine (SYN/ACK time)

• **Persistence**
  – Send all requests from one user session to the same system
DNS-based load balancing

• Round-Robin DNS
  – Respond to DNS requests with different addresses
    … or a list of addresses instead of one address
    but the order of the list is permuted with each response

• Geographic-based DNS response
  – Multiple clusters distributed around the world
  – Balance requests among clusters
  – Favor geographic proximity
  – Examples:
    • BIND with GeoDNS patch
    • PowerDNS with Geo backend
    • Amazon Route 53
The End
