KALMAN FILTERS AND DYNAMIC BAYESIAN NETWORKS

CHAPTER 15

Outline

- Time and uncertainty
- ♦ Inference: filtering, prediction, smoothing
- ♦ Kalman filters
- Dynamic Bayesian networks
- ♦ Particle filtering

Time and uncertainty

ation calculus!) The world changes; we need to track and predict it (remember situ-

in chemical plant E.g., autonomous taxi position, airplane position, level of chemicals

Basic idea: copy state and evidence variables for each time step

 \mathbf{X}_t = set of unobservable state variables at time te.g., $Rain_t$, $X_Velocity_t$, etc.

 \mathbf{E}_t = set of observable evidence variables at time te.g., $Umbrella_t$, $X_{Position_t}$, etc.

This assumes discrete time; step size depends on problem

Notation: $\mathbf{X}_{a:b} = \mathbf{X}_a, \mathbf{X}_{a+1}, \dots, \mathbf{X}_{b-1}, \mathbf{X}_b$

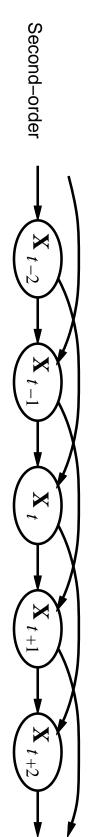

Markov processes Markov chains

Construct a Bayes net from these variables: parents?

Markov assumption: \mathbf{X}_t depends on **bounded** subset of $\mathbf{X}_{0:t-1}$

Second-order Markov process: $P(\mathbf{X}_t|\mathbf{X}_{0:t-1}) = P(\mathbf{X}_t|\mathbf{X}_{t-2},\mathbf{X}_{t-1})$ First-order Markov process: $P(\mathbf{X}_t|\mathbf{X}_{0:t-1}) = P(\mathbf{X}_t|\mathbf{X}_{t-1})$

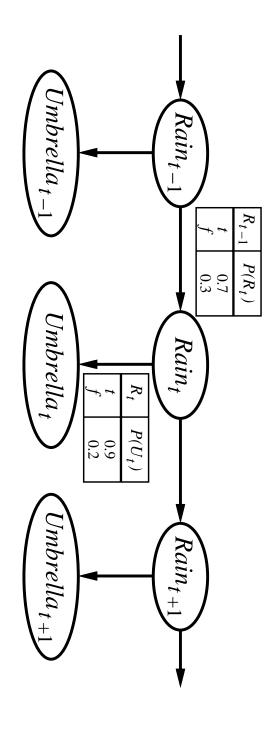

First-order

Sensor Markov assumption: $P(\mathbf{E}_t|\mathbf{X}_{0:t},\mathbf{E}_{0:t-1}) = P(\mathbf{E}_t|\mathbf{X}_t)$

sensor model $\mathbf{P}(\mathbf{E}_t|\mathbf{X}_t)$ fixed for all tStationary process: transition model $P(X_t|X_{t-1})$ and

Example

First-order Markov assumption not exactly true in real world!

Possible fixes:

- 1. Increase order of Markov process
- 2. Augment state, e.g., add $Temp_t$, $Pressure_t$

Example: robot motion.

Augment position and velocity with Batteryt

Inference tasks

Filtering: $P(X_t|e_{1:t})$ belief state—input to the decision process of a rational agent

Prediction: $P(\mathbf{X}_{t+k}|\mathbf{e}_{1:t})$ for k>0like filtering without the evidence evaluation of possible action sequences;

Smoothing: $P(\mathbf{X}_k|\mathbf{e}_{1:t})$ for $0 \le k < t$ better estimate of past states, essential for learning

Most likely explanation: $\arg \max_{\mathbf{x}_{1:t}} P(\mathbf{x}_{1:t}|\mathbf{e}_{1:t})$ speech recognition, decoding with a noisy channel

Filtering

Aim: devise a **recursive** state estimation algorithm:

$$\mathbf{P}(\mathbf{X}_{t+1}|\mathbf{e}_{1:t+1}) = f(\mathbf{e}_{t+1}, \mathbf{P}(\mathbf{X}_t|\mathbf{e}_{1:t}))$$

$$\mathbf{P}(\mathbf{X}_{t+1}|\mathbf{e}_{1:t+1}) = \mathbf{P}(\mathbf{X}_{t+1}|\mathbf{e}_{1:t},\mathbf{e}_{t+1})$$

$$= \alpha \mathbf{P}(\mathbf{e}_{t+1}|\mathbf{X}_{t+1},\mathbf{e}_{1:t})\mathbf{P}(\mathbf{X}_{t+1}|\mathbf{e}_{1:t})$$

$$= \alpha \mathbf{P}(\mathbf{e}_{t+1}|\mathbf{X}_{t+1})\mathbf{P}(\mathbf{X}_{t+1}|\mathbf{e}_{1:t})$$

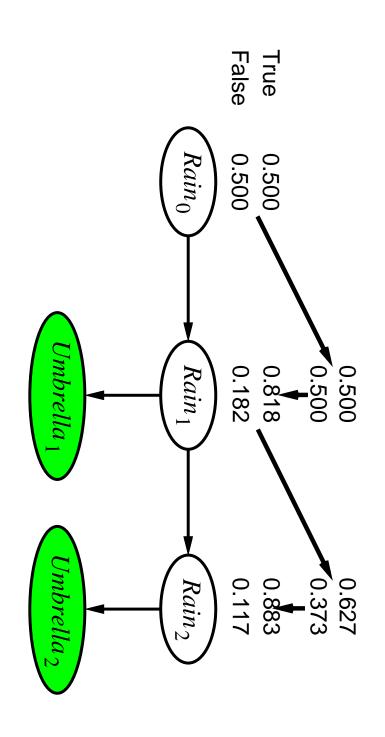

I.e., prediction + estimation. Prediction by summing out X_t :

$$\mathbf{P}(\mathbf{X}_{t+1}|\mathbf{e}_{1:t+1}) = \alpha \mathbf{P}(\mathbf{e}_{t+1}|\mathbf{X}_{t+1}) \sum_{\mathbf{x}_t} \mathbf{P}(\mathbf{X}_{t+1}|\mathbf{x}_t, \mathbf{e}_{1:t}) P(\mathbf{x}_t|\mathbf{e}_{1:t})$$

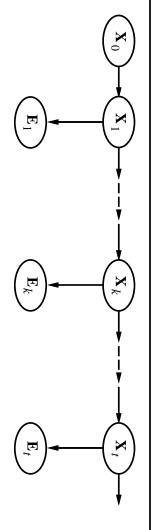

$$= \alpha \mathbf{P}(\mathbf{e}_{t+1}|\mathbf{X}_{t+1}) \sum_{\mathbf{x}_t} \mathbf{P}(\mathbf{X}_{t+1}|\mathbf{x}_t) P(\mathbf{x}_t|\mathbf{e}_{1:t})$$

 $\mathbf{f}_{1:t+1} = \text{Forward}(\mathbf{f}_{1:t}, \mathbf{e}_{t+1})$ where $\mathbf{f}_{1:t} = \mathbf{P}(\mathbf{X}_t | \mathbf{e}_{1:t})$ — forward message Time and space $\mathbf{constant}$ (independent of t)

Filtering example

Smoothing

Divide evidence $e_{1:t}$ into $e_{1:k}$, $e_{k+1:t}$:

$$\mathbf{P}(\mathbf{X}_{k}|\mathbf{e}_{1:t}) = \mathbf{P}(\mathbf{X}_{k}|\mathbf{e}_{1:k},\mathbf{e}_{k+1:t})$$

$$= \alpha \mathbf{P}(\mathbf{X}_{k}|\mathbf{e}_{1:k})\mathbf{P}(\mathbf{e}_{k+1:t}|\mathbf{X}_{k},\mathbf{e}_{1:k})$$

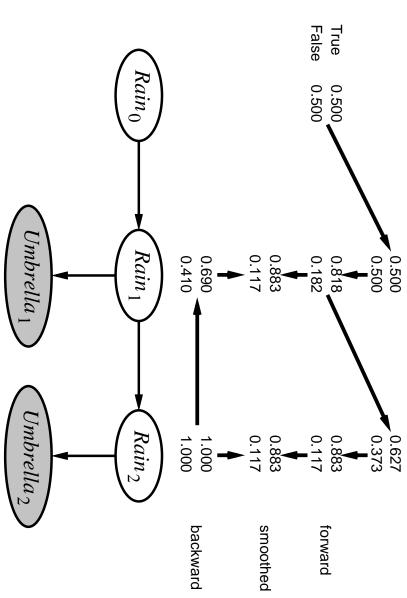

$$= \alpha \mathbf{P}(\mathbf{X}_{k}|\mathbf{e}_{1:k})\mathbf{P}(\mathbf{e}_{k+1:t}|\mathbf{X}_{k})$$

$$= \alpha \mathbf{f}_{1:k}\mathbf{b}_{k+1:t}$$

Backward message computed by a backwards recursion:

$$\begin{aligned} \mathbf{P}(\mathbf{e}_{k+1:t}|\mathbf{X}_k) &= \sum_{\mathbf{x}_{k+1}} \mathbf{P}(\mathbf{e}_{k+1:t}|\mathbf{X}_k, \mathbf{x}_{k+1}) \mathbf{P}(\mathbf{x}_{k+1}|\mathbf{X}_k) \\ &= \sum_{\mathbf{x}_{k+1}} P(\mathbf{e}_{k+1:t}|\mathbf{x}_{k+1}) \mathbf{P}(\mathbf{x}_{k+1}|\mathbf{X}_k) \\ &= \sum_{\mathbf{x}_{k+1}} P(\mathbf{e}_{k+1}|\mathbf{x}_{k+1}) P(\mathbf{e}_{k+2:t}|\mathbf{x}_{k+1}) \mathbf{P}(\mathbf{x}_{k+1}|\mathbf{X}_k) \end{aligned}$$

Smoothing

way Forward-backward algorithm: cache forward messages along the

Time linear in t (polytree inference), space $O(t|\mathbf{f}|)$

Most likely explanation

Most likely sequence eq sequence of most likely states!!!!

Most likely path to each \mathbf{x}_{t+1}

= most likely path to some \mathbf{x}_t plus one more step

$$\max_{\mathbf{x}_{1}...\mathbf{x}_{t}} \mathbf{P}(\mathbf{x}_{1},...,\mathbf{x}_{t},\mathbf{X}_{t+1}|\mathbf{e}_{1:t+1})$$

$$= \mathbf{P}(\mathbf{e}_{t+1}|\mathbf{X}_{t+1}) \max_{\mathbf{x}_{t}} \left(\mathbf{P}(\mathbf{X}_{t+1}|\mathbf{x}_{t}) \max_{\mathbf{x}_{1}...\mathbf{x}_{t-1}} P(\mathbf{x}_{1},...,\mathbf{x}_{t-1},\mathbf{x}_{t}|\mathbf{e}_{1:t})\right)$$

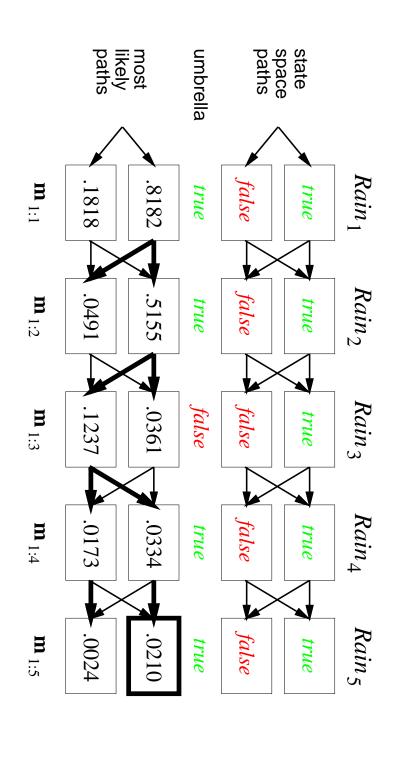

Identical to filtering, except $\mathbf{f}_{1:t}$ replaced by

$$\mathbf{m}_{1:t} = \max_{\mathbf{x}_1...\mathbf{x}_{t-1}} \mathbf{P}(\mathbf{x}_1, \dots, \mathbf{x}_{t-1}, \mathbf{X}_t | \mathbf{e}_{1:t}),$$

I.e., $\mathbf{m}_{1:t}(i)$ gives the probability of the most likely path to state i. Update has sum replaced by max, giving the Viterbi algorithm:

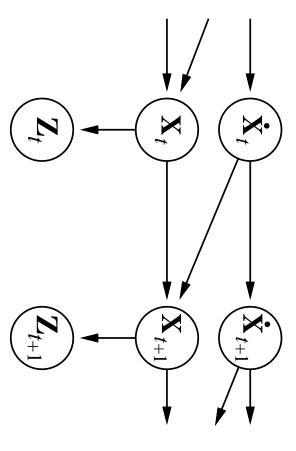

$$\mathbf{m}_{1:t+1} = \mathbf{P}(\mathbf{e}_{t+1}|\mathbf{X}_{t+1}) \max_{\mathbf{x}_t} (\mathbf{P}(\mathbf{X}_{t+1}|\mathbf{x}_t)\mathbf{m}_{1:t})$$

Viterbi example

Kalman filters

Modelling systems described by a set of **continuou**s variables, e.g., tracking a bird flying— $X_t = X, Y, Z, X, Y, Z$. Airplanes, robots, ecosystems, economies, chemical plants, plan-

Gaussian prior, linear Gaussian transition model and sensor model

Updating Gaussian distributions

Prediction step: if $P(X_t|e_{1:t})$ is Gaussian, then prediction

$$\mathbf{P}(\mathbf{X}_{t+1}|\mathbf{e}_{1:t}) = \int_{\mathbf{X}_t} \mathbf{P}(\mathbf{X}_{t+1}|\mathbf{X}_t) P(\mathbf{X}_t|\mathbf{e}_{1:t}) d\mathbf{X}_t$$

is Gaussian. If $P(X_{t+1}|e_{1:t})$ is Gaussian, then the updated distribution

$$\mathbf{P}(\mathbf{X}_{t+1}|\mathbf{e}_{1:t+1}) = \alpha \mathbf{P}(\mathbf{e}_{t+1}|\mathbf{X}_{t+1})\mathbf{P}(\mathbf{X}_{t+1}|\mathbf{e}_{1:t})$$

is Gaussian

Hence $\mathbf{P}(\mathbf{X}_t|\mathbf{e}_{1:t})$ is multivariate Gaussian $N(\boldsymbol{\mu}_t, \boldsymbol{\Sigma}_t)$ for all t

General (nonlinear, non-Gaussian) posterior grows unboundedly as

Linear dynamic system

Transition and sensor models:

$$x_{t+1} = \mathbf{F} \mathbf{x}_t + v_t$$

$$z_t = \mathbf{H} \mathbf{x}_t + w_t$$

$$v_t \sim N(0, \mathbf{\Sigma}_x)$$

$$w_t \sim N(0, \mathbf{\Sigma}_z)$$

 w_t is the measurement noise process (white Gaussian noise) v_t is the state noise process (white Gaussian noise) ${f F}$ is the matrix for the transition; ${f \Sigma}_x$ the transition noise covariance **H** is the matrix for the sensors; Σ_z the sensor noise covariance

17

General Kalman update

Transition and sensor models:

$$P(\mathbf{x}_{t+1}|\mathbf{x}_t) = N(\mathbf{F}\mathbf{x}_t, \mathbf{\Sigma}_x)(\mathbf{x}_{t+1})$$

$$P(\mathbf{z}_t|\mathbf{x}_t) = N(\mathbf{H}\mathbf{x}_t, \mathbf{\Sigma}_z)(\mathbf{z}_t)$$

Filter computes the following update:

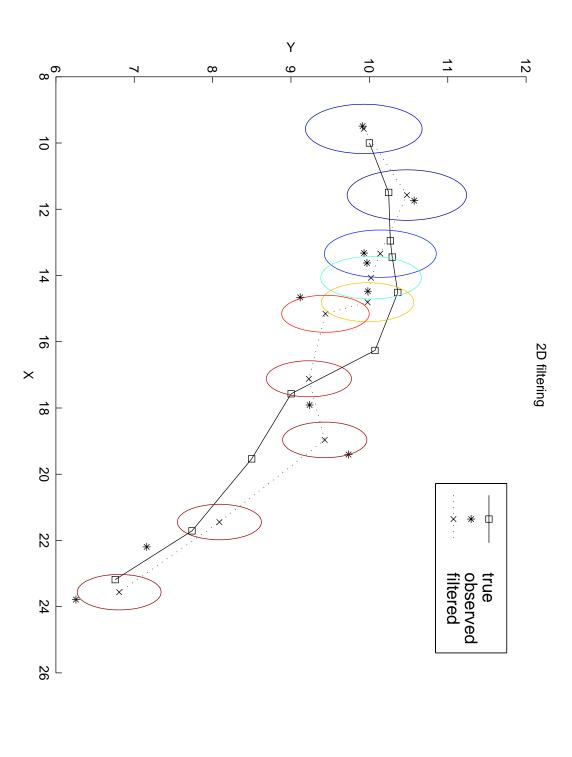

$$egin{aligned} oldsymbol{\mu}_{t+1} &= \mathbf{F} oldsymbol{\mu}_t + \mathbf{K}_{t+1} (\mathbf{z}_{t+1} - \mathbf{H} \mathbf{F} oldsymbol{\mu}_t) \ \Sigma_{t+1} &= (\mathbf{I} - \mathbf{K}_{t+1}) (\mathbf{F} \Sigma_t \mathbf{F}^{ op} + \Sigma_x) \end{aligned}$$

where $\mathbf{K}_{t+1} = (\mathbf{F} \mathbf{\Sigma}_t \mathbf{F}^\top + \mathbf{\Sigma}_x) \mathbf{H}^\top (\mathbf{H} (\mathbf{F} \mathbf{\Sigma}_t \mathbf{F}^\top + \mathbf{\Sigma}_x) \mathbf{H}^\top + \mathbf{\Sigma}_z)^{-1}$ is the Kalman gain matrix

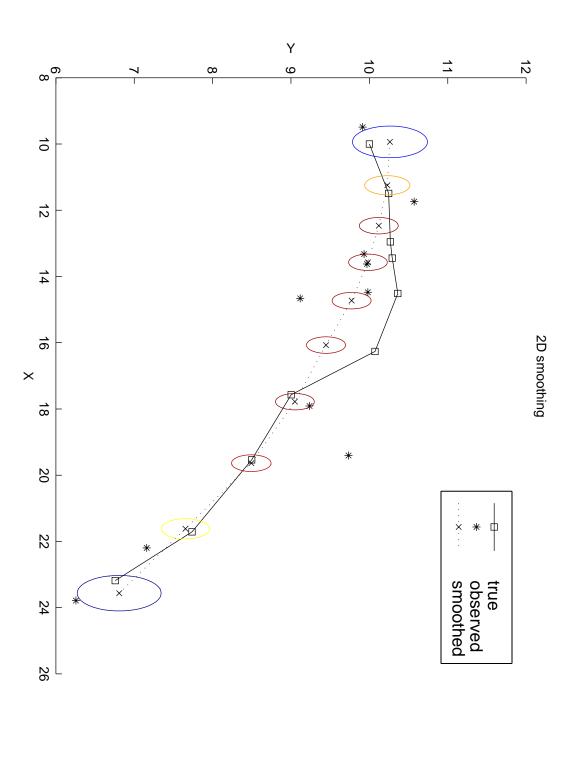

offline Σ_t and \mathbf{K}_t are independent of observation sequence, so compute

18

2-D tracking example: filtering

exam iple: smoothing

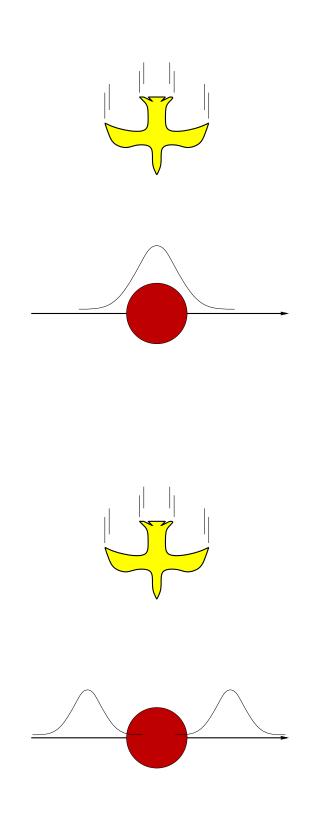

Where it breaks

Cannot be applied if the transition model is nonlinear

Extended Kalman Filter models transition as locally linear around

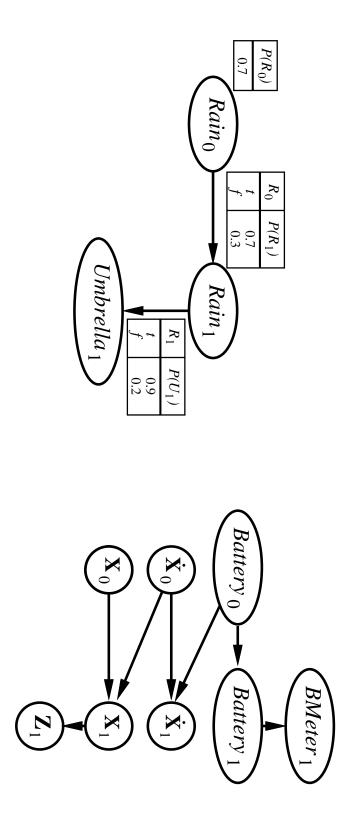

$$\mathbf{x}_t = \boldsymbol{\mu}_t$$

 $\mathbf{x}_t = \boldsymbol{\mu}_t$ Fails if systems is locally unsmooth

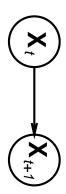

Dynamic Bayesian networks

 \mathbf{X}_t , \mathbf{E}_t contain arbitrarily many variables in a replicated Bayes net

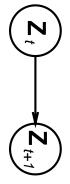

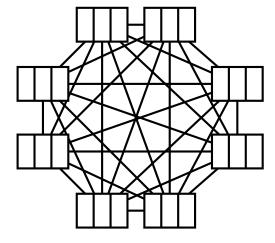

DBNs vs. HMMs

Every HMM is a single-variable DBN; every discrete DBN is an HMM

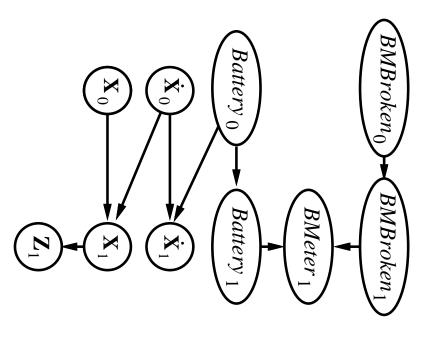

Sparse dependencies ⇒ exponentially fewer parameters; e.g., 20 state variables, three parents each DBN has $20 \times 2^3 = 160$ parameters, HMM has $2^{20} \times 2^{20} \approx 10^{12}$

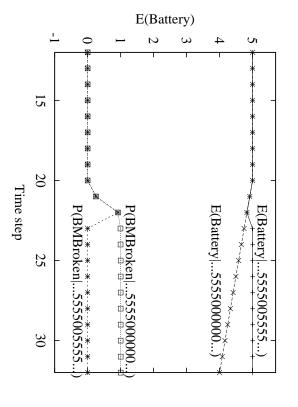

23

)BNs vs Kalman filters

Every Kalman filter model is a DBN, but few DBNs are KFs; real world requires non-Gaussian posteriors

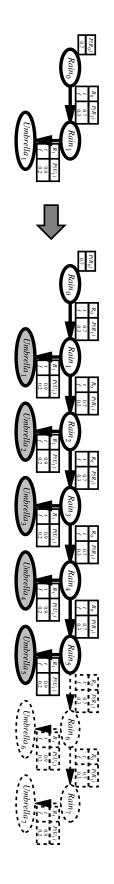

E.g., where are bin Laden and my keys? What's the battery charge?

Exact inference in DBNs

Naive method: unroll the network and run any exact algorithm

Problem: inference cost for each update grows with t

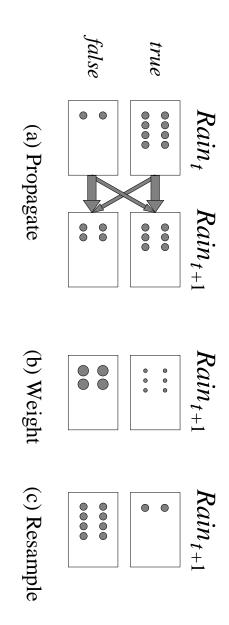

ination Rollup filtering: add slice t+1, "sum out" slice t using variable elim-

Largest factor is $O(d^{n+1})$, update cost $O(d^{n+2})$ (cf. HMM update cost $O(d^{2n})$)

Particle filtering

tracks the high-likelihood regions of the state-space Basic idea: ensure that the population of samples ("particles")

Replicate particles proportional to likelihood for et

Widely used for tracking nonlinear systems, esp. in vision

Also used for simultaneous localization and mapping in mobile robots 10° -dimensional state space

Particle filtering contd.

Assume consistent at time t: $N(\mathbf{x}_t|\mathbf{e}_{1:t})/N = P(\mathbf{x}_t|\mathbf{e}_{1:t})$

Propagate forward: populations of \mathbf{x}_{t+1} are

$$N(\mathbf{x}_{t+1}|\mathbf{e}_{1:t}) = \sum_{\mathbf{x}_t} P(\mathbf{x}_{t+1}|\mathbf{x}_t) N(\mathbf{x}_t|\mathbf{e}_{1:t})$$

Weight samples by their likelihood for \mathbf{e}_{t+1} :

$$W(\mathbf{x}_{t+1}|\mathbf{e}_{1:t+1}) = P(\mathbf{e}_{t+1}|\mathbf{x}_{t+1})N(\mathbf{x}_{t+1}|\mathbf{e}_{1:t})$$

Resample to obtain populations proportional to W:

$$N(\mathbf{x}_{t+1}|\mathbf{e}_{1:t+1})/N = \alpha W(\mathbf{x}_{t+1}|\mathbf{e}_{1:t+1}) = \alpha P(\mathbf{e}_{t+1}|\mathbf{x}_{t+1})N(\mathbf{x}_{t+1}|\mathbf{e}_{1:t})$$

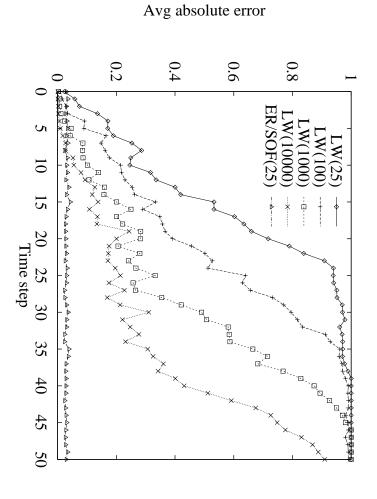

$$= \alpha P(\mathbf{e}_{t+1}|\mathbf{x}_{t+1})\sum_{\mathbf{x}_t} P(\mathbf{x}_{t+1}|\mathbf{x}_t)N(\mathbf{x}_t|\mathbf{e}_{1:t})$$

$$= \alpha' P(\mathbf{e}_{t+1}|\mathbf{x}_{t+1})\sum_{\mathbf{x}_t} P(\mathbf{x}_{t+1}|\mathbf{x}_t)P(\mathbf{x}_t|\mathbf{e}_{1:t})$$

$$= P(\mathbf{x}_{t+1}|\mathbf{e}_{1:t+1})$$

Particle filtering performance

at least empirically—theoretical analysis is difficult Approximation error of particle filtering remains bounded over time,

Summary

Temporal models use state and sensor variables replicated over

Markov assumptions and stationarity assumption, so we need

- transition model $P(\mathbf{X}_t|\mathbf{X}_{t-1})$
- sensor model $\mathbf{P}(\mathbf{E}_t|\mathbf{X}_t)$

all done recursively with constant cost per time step Tasks are filtering, prediction, smoothing, most likely sequence;

for speech recognition Hidden Markov models have a single discrete state variable; used

Kalman filters allow n state variables, linear Gaussian, $O(n^3)$ update

Dynamic Bayes nets subsume HMMs, Kalman filters; exact update intractable

Particle filtering is a good approximate filtering algorithm for DBNs
